

Subluxation: What is it?

Basic Concepts

Your central nervous system is responsible for sending and receiving messages to every cell, tissue, organ and system in the body. This is made possible by a vast communication network made up of the brain, spinal cord, and spinal nerves. This network is in charge of virtually every function in your body and determines whether you enjoy good health or fall prey to disease. The central nervous system is so important that nature built a bony armor around it, your skull and your spinal column. However, even with this "inborn protection" our nervous system can experience interference, injury, or disturbance. We call this damage to our nervous system a **SUBLUXATION**.

What is the effect of subluxation?

Your examination has determined that you have one or more subluxations affecting your nervous system. This could potentially be a very serious threat to your continued overall health and well being.

Subluxation can have devastating effects on your overall health especially in the long run. **Like a cut or damaged phone line, subluxation disrupts your body's communication system.** When we look at your scans we are looking at a disturbance of your nervous system that interferes with the ability of your central nervous system to communicate with and control your body. Our primary goal is to detect and correct the subluxations that are interfering with your nervous system and thus allow your body to heal and establish a healthier you. It is impossible for someone to live a quality, optimal life through an impaired nervous system.

How do subluxations become chronic or even permanent?

How would you know if you have a subluxation? You wouldn't! Like heart disease, subluxations are often called "**The Silent Killer**" because of their nature of not causing any pain until they are quite progressed. Subluxations usually go undiagnosed for many, many years as they deteriorate your overall health potential in the process. Subluxations can be **Acute, Chronic, or Permanent** depending on the amount of time they have gone unnoticed and the amount of damage they have produced. Just as you wouldn't know whether you had an early cavity in your tooth without a dental examination, there are no early symptoms of subluxation. If you wait for tooth pain to see the dentist the price of neglect can be expensive and result in the permanent loss of teeth.

You may have family members at home right now that do not have symptoms, but they may be subluxated and neglecting their nervous system. Individuals of all ages can and should be checked for subluxations. **It is easier to grow healthy children than to repair damaged adults.** Have your family members been checked for nerve interference or subluxations?

Remember, during your first month of care **we offer nervous system examinations** to any and all of your family members for **FREE**. Make an appointment for them today.
